ACKNOWLEDGEMENTS

This agricultural sector review was commissioned by the European Bank for Reconstruction and Development (EBRD) and carried out by the Investment Centre Division of the United Nations Food and Agriculture Organization (FAO) under the cooperation agreement between the two institutions. It was jointly financed by the EBRD's Early Transition Countries (ETC) Fund and FAO.

The study was completed in two stages. Six background studies were initially drafted on agri-food policies (Serova, 2010), value chains (Punda, 2010a and 2010b), foreign trade (Prikhodko, 2010), agricultural services and marketing (Stanchin, 2010a), and food processing and agricultural taxation (Stanchin, 2010b). The background studies were used to prepare the final study.

The main authors of this study were Zvi Lerman, Agricultural Economist, Hebrew University; Dmitry Prikhodko, Agricultural Economist, Investment Centre Division, FAO; Inna Punda, Value Chain Specialist, Investment Centre Division, FAO; David Sedik, Senior Agricultural Policy Officer, Regional Office for Europe and Central Asia, FAO; Eugenia Serova, Senior Advisor to the Division Director, Investment Centre Division, FAO; and Johan Swinnen, Professor, Catholic University of Leuven. Other contributors included Giovanni Muñoz, Land and Water Development Engineer, Investment Centre Division, FAO; Ivan Stanchin, Agricultural Economist; and Kristine Van Herck, Research Assistant, Catholic University of Leuven. Except when noted, all the data in this study are based on official sources from the Turkmen National Institute of Statistics.

The study was reviewed by Iride Ceccacci, Economist, Chief Economist Office, EBRD; Peter Goodman, Senior Agricultural Specialist, World Bank; Heike Harmgart, Senior Economist, Chief Economist Office, EBRD; and Emmanuel Hidier, Senior Economist, Investment Centre Division.

The FAO and the EBRD team would like to thank all Turkmen officials and other stakeholders met during the field visits for their time and insights. Sincere thanks are also extended to Claudio Gregorio, Service Chief, Near East, North Africa, Europe, Central and South Asia Service, Investment Centre Division, FAO; as well as Nada Zvekcic, Communications Officer, Investment Centre Division, FAO; and Genevieve Joy, Project Support Specialist, Investment Centre Division, FAO for the support they provided to the publication of this study.

INTRODUCTION

The main objective of this agricultural sector review in Turkmenistan is to establish an initial policy discussion with the Government of Turkmenistan to point to areas where investment opportunities are most likely to arise in the future.

The first chapter discusses the primary agricultural production in Turkmenistan. In addition, it compares Turkmenistan with its immediate neighbours in Central Asia when relevant, illustrating that Turkmenistan should be placed in the same category as the small Central Asian states and southern Kazakhstan due to the importance of its natural resources.

The second chapter discusses the next stage in the agricultural value chain—agricultural commodity and input markets. This chapter describes the state control mechanisms for four strategic crops—cotton, wheat, sugar beets, and rice—on one side and the relatively unfettered and unorganized individual sector on the other.

The third chapter analyzes the food processing sector in Turkmenistan. It discusses the importance of the state and private sector and provides case study evidence on two important supply chains: bread & milling and dairy.

The fourth chapter discusses the importance of foreign trade in Turkmenistan and more specifically trade in agri-food products.

The fifth chapter describes the agricultural policy framework in Turkmenistan, including existing output and input price regulation, investment and trade policy.

The final chapter includes a number of conclusions and recommendations with respect to the investment climate and potential market development opportunities.

EXECUTIVE SUMMARY

An economy driven by the energy sector, but with a strong prevalence of agricultural labour. In 2008, the Turkmen gross domestic product (GDP) per capita was USD 3 918¹, closer to the level of other energy-based economies such as Azerbaijan and Kazakhstan than the GDP per capita of Turkmenistan's agrarian neighbours. Turkmenistan's agricultural sector represents only 19 percent of the country's GDP; but the country has a high share of rural population (58 percent) and agricultural labour (48 percent of the total labour force). Moreover, as Turkmenistan, like other Central Asian economies, has been unable to generate sufficient jobs outside of agriculture, rural population and agricultural employment have increased.

Harsh natural conditions for agricultural production. Agricultural land accounts for more than 80 percent of Turkmenistan's total territory. However, Turkmenistan is an arid country and most of its agricultural land is desert pasture with very little cultivable land. Its agriculture is highly dependent on irrigation. In fact, Turkmenistan is the only Central Asian country where the irrigated area in 2007 to 2008 was substantially above the 1990 level.

Uncertainties surrounding the extent of agricultural recovery. All Commonwealth of Independent State (CIS) countries experienced a decline in agricultural production during the early 1990s. At the end of the 1990s, however, this transitional decline was followed by a phase of recovery. In the case of Turkmenistan, the extent of this recovery is difficult to assess due to the uncertainties associated with national production statistics, which conflict with independent sources.

Crop production under strong state control. Unlike other CIS countries, Turkmenistan has almost no large agricultural enterprises engaged in primary production. The large structures of the Soviet period were transformed into peasant associations consisting of individual leaseholders. Peasant associations are subjected to state orders, however: they are obliged to sell their output and buy their inputs through state channels. This is particularly true for crop production, which is heavily controlled by the state, while the livestock sector operates on a more private basis.

¹ The World Bank.

A sharp increase in livestock production. Prior to 1990, Turkmenistan's agriculture was characterized by a relatively high share of crop production as opposed to a correspondingly low share of livestock production. After 1992, in contrast with what happened in most CIS countries, the contribution of livestock production to national output grew. Milk production grew very sharply from 436 000 tonnes in 1990 to 2 100 000 tonnes in 2007, partly due to a significant improvement in milk productivity: yields rose from pre-1998 levels of 1 300 kg per cow to 2 000 kg per cow in 2006 to 2007. In that same period of time, meat production tripled.

The remaining importance of cotton production. During the Soviet Union, Turkmenistan's agriculture was characterized by the monoculture of cotton. The country ranked second after Uzbekistan in cotton production among the six cotton republics of the Former Soviet Union. The situation began to change rapidly after 1990, when the government started to stimulate wheat production in order to achieve a higher degree of national food self-sufficiency. However, despite this relative decline of cotton production, Turkmenistan remains a significant cotton producer in the region.

A limited horticultural production. Turkmenistan produces few vegetables, in part because of its arid climate but mainly due to the competition with staple crops for cultivatable land. The country produces about 620 thousand tonnes of vegetables (compared to more than 6 million tonnes in Uzbekistan²) and scarce quantities of fruits (150 thousand tonnes as compared to 2.2 million tonnes in Uzbekistan) although melons and grapes are more common with a production of respectively 254 and 222 thousand tonnes in 2008.

Little value added in the food chain. The food processing industry in Turkmenistan accounts for 9 to 10 percent of GDP, with cotton fibre adding another 1 to 2 percent of GDP (data for 2000 to 2007). Since the general production decline of the early 1990s, only the production of bread products and flour, processed fruits and vegetables and non-alcoholic beverages has increased significantly compared to pre-reform levels of output. The output of the meat and dairy industry is still much less than during the pre-reform period. With the background of rapidly increasing livestock production, this means that the livestock sector has a predominantly subsistence nature.

² Sources: FAOSTAT for Uzbekistan and National Institute of State Statistics and Information for Turkmenistan.

Dualistic agricultural policies. The agricultural policy of Turkmenistan reflects the duality of the political and economic system in the country. On the one hand, the state tightly controls some so-called strategic sectors, while it has a more permissive approach to private business in other sectors. Four agricultural subsectors have been almost unreformed since Soviet times: grain, cotton, rice and sugar beets. For these four crops, almost all measures from the Soviet arsenal are still applied today: mandatory state deliveries, state fixed prices, state supply of main inputs at discounted prices and concessional state lending.

Agricultural associations with ambiguous roles. The food industry is subject to state licensing, and this has an impact on the development of the sector. Another feature of Turkmenistan's industrial policy, which applies to the food industry, is the mandatory syndication of companies: all the enterprises of a branch of the industry are united in a union or association. The main task of these associations is to implement state policies rather than lobby the interests of their members with the state. Agricultural associations consider themselves governmental bodies and are often established in former Soviet ministries and agencies.

The emergence of small-scale food processors. Although the food processing companies of the pre-Soviet period were not privatized during the transition period, private processors—predominantly small-scale—have emerged in most sectors of the food processing industry including meat, dairy, vegetable canning, and bakery. While flour and other milled products appear to be controlled by a virtual monopoly of state processors, the share of private processing ranges from 30 to 50 percent for meat and dairy products, and from 80 to 90 percent for bread and canned vegetables.

The negative protection of agricultural production. The Turkmen farmers who produce under state orders receive input subsidies but they also receive low prices for their production. Altogether, their income would be higher if they were paid at world market prices and received no subsidies. Estimates show that farmers are implicitly taxed in Turkmenistan. The nominal protection rate, calculated on the basis of market exchange rates for wheat and cotton, is strongly negative, although improving. It increased from -86 to -27 percent between 2005 and 2009 from for wheat and from -60 to -37 percent for cotton.

Agricultural reforms still to be introduced. Turkmenistan's current agricultural policy is characterized by the fact that the country has not implemented the economic reforms that were adopted to various extents in other transition countries. Over recent years, the political will for reforms and a more market-oriented economy has been emerging. However, most analysts agree that these reforms will be slow and the elimination of the distortions of the economic policy conducted with extreme dirigisme by the previous government will require a long period of time. Despite the many declarations of reform by the current leadership, the overall economic environment in Turkmenistan remains highly restrictive and lacks many of the institutions that would be required to support a market economy. Although the private sector is important for some agricultural products, the state sector still heavily dominates the production and processing of four strategic commodities (cotton, wheat, sugar beets and rice). Moreover, there are few institutions supporting the private sector. There are no private commercial banks in Turkmenistan as all banks are state-owned and the availability of credit for entrepreneurial activities outside of the state order system is limited, as banks are not adapted to working with small businesses.

Limited agricultural trade with the rest of the world. Turkmenistan does not belong to any existing international or regional multilateral trade system. It is also the only country of the Former Soviet Union that has not applied for membership in the World Trade Organization (WTO). Foreign trade is de facto controlled by the state through the obligation to register all wholesale and export-import contracts with the State Raw Material and Commodity Exchange. As a result, the Turkmenistan economy is relatively isolated.

An emerging trend of net agri-food imports. However, Turkmenistan has maintained a positive trade balance for many years, and its trade surplus has grown since the early 2000s. Mineral fuels, in particular natural gas, are by far the dominant export and a major source of export revenues. Cotton lint is the distant second item, accounting for a mere 2 percent of export revenues. In global agricultural trade, Turkmenistan plays an insignificant role and its cotton accounts for only 3 percent of global production. Turkmenistan had a positive agri-food trade balance in 2004-2007. However, owing to the surge in global food prices in 2007-2008, the country became a net importer in 2008. Kazakhstan, the Russian Federation and Ukraine are the main exporters of food and agricultural products to Turkmenistan, supplying

mostly wheat, flour, beverages, confectionary products, tobacco and sugar. Turkey has been by far the most important export destination for Turkmen cotton, hides and wool products in the last five years.

Highly centralized decisions for foreign investment. Large foreign investments including investments in the food industry can be implemented only after the personal decision of the President of the Republic. The President also allocates plots of land for green field investment. In the last 15 years, there has been no allocation of land for the food industry but the new President recently endorsed the construction of 48 new food enterprises, mainly dairy, fruit and vegetable processing companies. Foreign investors can bid, but their chances to win are usually determined by agreements between Turkmenistan and other countries. So far, foreign investors have been attracted mainly by the following sectors: wholesale and retail, manufacturing, construction, agriculture, forestry and services.

Lack of sector and company information to inform investment decisions. While there may be opportunities, constraints for investment in Turkmenistan's agri-food sector are many. First, accurate information on the various subsectors and on the financial performance of individual enterprises is not publicly available, which make investment decision-making extremely difficult, even compared to other CIS countries. At the sector level, the information gathered for this review was obtained in the face of great difficulties, exceeding those encountered in other CIS countries

Uncertain ownership and contractual rights. There is only limited information on the state of basic institutions in Turkmenistan and it is unclear how the situation is with respect to ownership rights, and the security of these rights, and contract enforcement, which are crucial issues for both domestic and foreign investors. It appears that some decisions are still being taken on an ad hoc basis (e.g. the sudden confiscation of land from daikhan farms based on farm performance, despite the strong growth of the private sector), which implies risk and uncertainty.

Supporting agri-food small and medium-sized enterprises (SMEs) in selected sectors. The above limitations clearly restrict the potential scope of EBRD operations in Turkmenistan's agri-food sector. Without a more supportive legal environment, equity participation on a large scale would be risky. Less risky would be loans to private

SMEs involved in the baking, meat processing, fruit and vegetables processing and dairy sectors. Investments in private SMEs in the confectionary sector, beverages (e.g. juices) and retail food stores could also offer reasonably good prospects given the projected growth in Turkmen consumers' incomes. Within this limited window of operations, retail food stores are less risky as they are less exposed to state regulations and small scale agriculture. By contrast, for food processing SMEs, there are two main risk factors that can impact operations: the influence of state regulations and the dependence on small scale agricultural suppliers.

Encouraging policy reforms. In addition, it could be useful for the EBRD to engage in policy discussions with the government of Turkmenistan to promote less state control and allow market institutions to develop, which would eventually result in more private investment. The Turkmen Government could be encouraged to remove regulations that specifically discourage investment. In the agri-food sector for example, it would be advisable to shift from GOST standards to more modern standards compatible with a market economy and the principles of the WTO international trading system, or else to allow the establishment of marketing cooperatives.

■■■■ Agricultural production

Importance of the agricultural sector

Turkmenistan is a Central Asian country with a land surface of 491 200 km² and it is the fourth largest country among the CIS after the Russian Federation, Kazakhstan and Ukraine. Although a large proportion of the land surface is considered to be agricultural land, only 4 percent of this agricultural land (1.7 million hectares [ha]) is cultivable, compared to 60 percent to 80 percent in the Russian Federation and Ukraine or about 25 percent in the other Central Asian countries. The remaining 96 percent of agricultural land in Turkmenistan is desert pasture.

Turkmenistan has a population of about five million people, which is comparable to the populations in Armenia, Georgia and Azerbaijan. Nearly 60 percent of the population lives in rural areas compared to less than one-third in the Russian Federation and Ukraine. The effective population density in Turkmenistan is high: there are 0.5 ha of arable land per rural resident compared to 2 to 3 ha in Ukraine and the Russian Federation (Table 1.1).

Map of Turkmenistan

Source: United Nations Department of Peacekeeping Operations, Cartographic Section (January 2004).

In Turkmenistan, the agricultural sector is still a prominent economic sector with a high share of the rural population (58 percent) and a high share of agricultural labour in the total labour force (48 percent) (Table 1.2). During transition, agricultural labour tended to increase in the Central Asian countries, while it generally decreased in the European countries. This trend is closely correlated with rural population growth and more general population growth.¹ The strong positive correlation between agricultural labour and total population is a reflection of the fact that in general the Central Asian economies have been unable to generate enough jobs outside agriculture to attract new entrants into the non-agricultural labour force.

The agricultural sector represents only 19 percent of GDP in Turkmenistan. This is significantly lower than in the other agrarian Central Asian countries, mainly due to its energy-based economy (oil and gas exports). The Turkmen GDP per capita was USD 3 918 in 2008, which puts it closer to the other energy-based economies, such as Azerbaijan and Kazakhstan, than to its agrarian neighbours.

Overall, the Central Asian countries are highly agrarian (Table 1.2). The four Central Asian countries, excluding Kazakhstan, are at the top of the agrarian ranking, followed by the three Transcaucasian states (Armenia, Georgia, Azerbaijan) and Moldova. Kazakhstan is close to the bottom of the agrarian ranking, although its agrarian index is still substantially higher than the indexes in the Russian Federation, Ukraine or Belarus. In general, economies with a high agrarian index have a lower GDP per capita, but the presence of natural resources in Turkmenistan makes the country an exception.

Land tenure and farm structure

Land tenure

Turkmenistan's agricultural transition has been marked by very slow and gradual reforms that are intended to achieve a limited degree of market orientation while maintaining strong involvement of the state in major policies.

¹ Over the past decade there has been rapid population growth in Turkmenistan. The population grew at a rate of 4 percent per year between 1990 and 2000, but between 2000 and 2008 the growth rate slowed down to 0.6 percent. In the coming years, the population is projected to rise from 5.6 million in 2008 to 6.4 million in 2015 (annual average growth rate of 1.8 percent) (see Annex 1.1. for detailed data).

Table 1.1. Selected characteristics of Central Asian countries with the Russian Federation and Ukraine for comparison*

	Country area, thousand km ²	Ag land in use, million ha	Population, million	Population density, per km ²	Arable land per rural resident, ha	Arable land, % of ag land	Irrigated, % of arable ^a

Source: Interstate Statistical Committee of the CIS - CISSTAT (2009).

In terms of land reform and farm restructuring, reforms have mainly focused on two aspects: the distribution of land to individual farms and restructuring of the large farms inherited from the Soviet period. A chronology of presidential decrees and laws concerned with land reform is given in Annex 1.2. The central features of Turkmenistan's reforms have been:

- (i) Liberalization of state control over household plots and an augmentation of land allocated to these households;
- (ii) An aborted experiment of increasing and then sharply decreasing land allotted to "private" daikhan (or peasant) farms;
- (iii) Restructuring of traditional large farms into "peasant associations" that lease state-owned land to farmers while maintaining state provision of inputs and state procurement of agricultural output.

These changes led to the creation of three groups of agricultural producers: traditional household plots, daikhan farms and peasant associations. Table 1.3 summarizes the main characteristics of these three groups of producers.

In general, household plots and daikhan farms are considered to be private farms, while peasant associations (and the land cultivated by the leaseholders in these associations) are considered to be the collective sector. However, it is important to keep in mind that there is an unclear line between the collective and the private sector in Turkmenistan.

Unlike the other CIS, Turkmenistan has almost no large agricultural enterprises engaged in primary production. These large enterprises are transformed in peasant associations consisting of individual leaseholders. Peasant associations, however, are subject to state orders and are obliged to sell their output and buy their inputs through state channels.

In general, the leaseholders have almost no decisive power on what they produce, which seeds they use, when they harvest, etc. As such they cannot be seen as voluntary associations of smallholders who work together in order to reach economies of scale nor as collective farms similar to the farms that existed during the Soviet period.

Table 1.3. Main characteristics of the three groups of agricultural producers in Turkmenistan

	Households	Daikhan farms	Leaseholders
Land ownership	Privately owned	Long-term lease from the state	Lease from the peasant association
Land quality	Arable	Arable + unirrigated desert	Arable
Farm size	0.5-1 ha	20-50 ha	3-10 ha
Crop mix	Horticulture, some grain	Grain, cotton, some horticulture	Grain, cotton, some horticulture
Livestock	Yes	Very little	In household plots only
Orientation	Semi-subsistence	Commercial	Commercial
State orders	None	None; "voluntary" for strategic commodities	Obligatory for strategic commodities; none for other
Sales arrangements	Market	State channels (direct), market for surplus and non-strategic product	State channels (through peasant association), market for non-strategic products
Farm inputs, services	Market	State channels (direct), market	State channels (through association), market

Farm structure

Agricultural producers, which comprise peasant associations with their leaseholders, household plots, daikhan farms and other producers, control nearly 70 percent of Turkmenistan land area (Table 1.4). This includes almost all cultivable land (94 percent) and a large share of pasture land (78 percent). About 20 percent of the land is in the state reserve, and the remaining 10 percent is managed by non-agricultural users. The state reserve in 2002 was two-thirds pasture land, one-third non-agricultural land and only a negligible amount of cultivable land, which makes it unsuitable for potential land redistribution.

Table 1.5 shows the tenure structure of cultivated land in Turkmenistan in 2008. The share of land cultivated by peasant associations is 94 percent, of which the majority are associations of leaseholders (92 percent), while collectively cultivated land represents only 2 percent. The private sector (household plots and daikhan farms) represents only 6 percent of the cultivated land in 2008.

Table 1.4. Structure of total land use in Turkmenistan (in %)

	1998	1999	2000	2005	2007	2008
Total land in use, '000 ha	49 403	49 403	49 121	49 121	49 121	49 121
Agricultural producers	69.9	69.8	70.2	68.9	68.5	68.1
Associations*	68.6	68.6	69.0	67.2	67.0	66.8
Other producers**	1.0	1.0	0.9	1.6	1.5	1.2
Daikhan farms	0.2	0.2	0.2	0.1	0.0	0.1
State reserve	19.7	19.7	20.0	20.5	20.7	21.0
Non-agricultural users	10.5	10.5	9.8	10.6	10.8	10.9

* Land allocated to leaseholders, land in household plots, and land in joint use; ** Subsidiary farms maintained by various ministries, experimental stations, teaching farms, state enterprises. Since 2004 includes also "shareholder companies" or "joint stock companies" as a new organizational form.

Land in individual use: household plots and daikhan farms. During the Soviet period the private sector was represented by household plots, which in total controlled about 40 000 hectares, of which 75 percent was irrigated land. The decision in April 1991 to augment the land allocated to household plots increased the total area cultivated by the private sector from about 50 000 hectares in 1990 to 125 000 hectares in 1995 and then more gradually to 135 000 hectares in 2007 (Figure 1.1, Annex 1.3). In relative terms, the household plots doubled their share of cultivable land from 3 percent in 1990 to a steady 6 percent since 1992.

A new private sector component began to emerge alongside household plots in 1993 (Figure 1.1, Annex 1.3). These were daikhan farms established by enterprising individuals outside the collectivist framework. Land was allocated to daikhan farms without payment, as a grant, but it was mainly unirrigated and uncultivable land such that

daikhan farms were forced to reclaim desert land at their own expense. The poor quality of land in daikhan farms is illustrated by the following comparison with land in household plots: in 1993–1995 cultivable land in daikhan farms was only 30 to 40 percent of the holdings, compared to 80 percent in household plots.

Despite the physical obstacles and the marginal quality of land allocated to daikhan farms, individuals began to apply in increasing numbers for an independent plot of land outside the collective framework. The number of daikhan farms rose from zero in 1992 to 7 000 in 2000–2001. The land allocated to daikhan farms rose from zero in 1992 to 100 000 hectares in 1995 and peaked at 116 100 hectares in 1998, the year when the private sector (daikhan farms and household plots combined) reached nearly 10 percent of all cultivable land in Turkmenistan.

Since 1998, the daikhan farms have lost 80 percent of their holdings (dropping to 25 300 hectares in 2 450 farms in 2008) as the authorities began to enforce the legal provisions that made land grants conditional on satisfactory farming performance (land cannot be uncultivated for more than two years). As a result, the share of the private sector (household plots and daikhan farms combined) decreased from 10 to 7 percent of cultivable land in 2006 (Figure 1.2). It then rebounded to 9 percent due to an increase in the allocation of land to household plots.

Land in collective use: peasant associations. Today peasant associations control nearly 95 percent of cultivated land in Turkmenistan (sown areas plus land under vineyards and orchards). Between 1997 and 2007, the peasant associations had three main roles. First, they were “guardians” or “administrators” of state-owned agricultural land that was distributed to leaseholders. Second, they became the municipal authority responsible for maintaining rural infrastructure in the villages. In return, they received a payment from the leaseholders (percentage of production revenue). Third, they were the conduit for transmitting state orders to the leaseholders and enforcing compliance.

Until 2007, the parastatal agro-service providers signed supply and marketing contracts for strategic commodities directly with more than 100 000 leaseholders and Daikhan Bank, a central agricultural bank with a wide network of 55 branches in all district centres and 400 offices in all peasant associations. As of mid-2007 the system was streamlined by stipulating two-level contracting arrangements. The peasant association concluded lease contracts with its members.

Figure 1.2. Structure of cultivable land in household plots and daikhan farms, %

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

These contracts included production targets based on the state orders received by the association and the resource base of each leaseholder, guaranteed provision of inputs in appropriate quantities, and stipulated payment (at fixed state prices) for deliveries of farm products to the association. The association in turn signed agreements with agro-service providers and Daikhan Bank, which ensures financing through the association's bank account, delivery of inputs to the association and collection of farm products from the association. The association interfaces with the leaseholders, distributes credit, cash and inputs, and collects their output.

As indicated before, the large leaseholder sector cannot be regarded as a full-fledged extension of the private sector because leaseholders continue to be subject to state orders and are tied by restrictive links to state-controlled service providers. As such, Turkmenistan's leaseholder agriculture, while close in many attributes to family farming, occupies an intermediate position in the spectrum between private and corporate farms.

The role of the private sector in crop production. Increased allocation of land to the private sector—first through augmentation of household plots in 1992 and subsequently through creation of independent daikhan farms—has naturally resulted in a significant increase of the private sector's share in crop production. Figure 1.3. shows that the aggregate value of crops produced in the private sector increased from about 10 percent of total Gross Agricultural Output (GAO) in 1996 to 60 percent in 2007.

Vegetables and fruit, including potatoes and melons, were the traditional crops produced by household plots during the Soviet times. The share of vegetables produced by the private sector increased from less than 20 percent in 1990 to nearly 95 percent today (Figure 1.4). In terms of the production of fruit and grapes, household and daikhan farms produce more than 80 percent of the output, up from 20 percent to 30 percent in the early 1990s (Figure 1.4).

Figure 1.3. Crop production by farm type, 1996-2008

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

Figure 1.4. Share of the private sector in the production of main crops 1990-2008

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

The creation of daikhan farms in the mid-1990s led to an increase in the grain and cotton production by the private sector. Official statistics indicate that by the early 2000s the private sector was producing one-third of Turkmenistan’s wheat and cotton (Figure 1.4). Yet these figures have been drastically revised downward and today the share of private grain and cotton production is negligible, down from 40 percent in 2001-2005. It is unclear to what extent the rapid decline in the number of daikhan farms played a role in explaining these dramatic changes or whether unreliable statistics are at the origin of these changes.

In general, the private sector achieves higher yields than the peasant associations (see Annex 1.4 for detailed data). Figure 1.5 shows the average yield ratios between private farms and peasant associations for the main crops. For grain, melons, and grapes private farms achieve average yields that are more than double the yields achieved in peasant associations.

The role of the private sector in livestock production. Since 1997, the share of the private sector in livestock production has stabilized at around 90 to 95 percent of total livestock output and 90 percent of the livestock herd (Table 1.6 and Figure 1.6).

Figure 1.6. Milk yields in farms of different types (kg per cow per year) and share of cows in private farms (percent), 1985-2007.

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

Until the early 1990s, milk yields achieved by collective farms were twice the milk yields in individual farms (household plots at that time). Thus, yields in collective farms averaged around 2 000 kg per cow per year, compared with 1 000 kg per cow per year for household plots (Figure 1.6). The situation began to change after 1992-1993, when augmentation of household plots resulted in a substantial increase of the livestock herd and especially the number of cows kept by rural families. The improved feed base on larger plots led to an increase in milk productivity, which rose from 1 000 kg per cow to around 2 000 kg per cow in 2007. The milk productivity in the peasant associations was less than 1 000 kg per cow between 1994 and 1998, a drop of 50 percent.

Agricultural input use: land, labour and water

Agricultural land

Arable land accounts for more than 80 percent of Turkmenistan's total territory. However, Turkmenistan is a desert country. Most of its arable land is desert pasture, with very little cultivable land (see detailed data in Annex 1.5). Owing to an expansion of the irrigation network, the share of cultivable land excluding pasture has been increasing over the past decades, from 1.5 percent of agricultural land in the 1960s to 4 percent in the 1990s and 2000s. The remaining 96 percent of agricultural land is pasture land.

Turkmenistan is the only Central Asian country where the irrigated area in 2007-2008 is substantially above the 1990 level. The irrigation efforts in Turkmenistan persisted after its independence and stopped in 1994, producing a one-time boost in irrigated area followed by stability at a new increased level. Three of the five Central Asian countries – Kazakhstan, Kyrgyzstan and Uzbekistan – displayed dramatic decreases in cultivated land after 1990, presumably due partly to the abandonment of unproductive or inaccessible pastures (Figure 1.7) to the increase in energy costs, and the abandonment of irrigated lands. Tajikistan, as well as a group of six other CIS countries (Armenia and Georgia in the Transcaucasus, The Russian Federation, Ukraine, Moldova, and Belarus in the European CIS), are characterized by stability of agricultural land since 1990.

Figure 1.7. Evolution of agricultural land in CIS 1980-2008

Source: Interstate Statistical Committee of the CIS - CISSTAT (2009).

Agricultural employment

Agricultural employment increased substantially from 600 000 people in 1990 to almost 1 million people in the recent years – or an increase of nearly 70 percent. The share of agricultural employment in total employment has remained stable at about 50 percent since the end of the 1990s (after having steadily increased from 40 percent in 1980). Detailed data for agricultural labour in Turkmenistan up to 2007 are given in Annex 1.6.

Water resources and irrigation

The main source of water for Turkmenistan is the Amu Darya and most of its flow is withdrawn by Turkmenistan and Uzbekistan along their common border. Turkmenistan diverts more than 30 percent of the total flow of Amu Darya for its use, mainly through the Karakum Canal. Turkmenistan's total water intake includes 26 billion cubic metres (cu.m) of surface runoff plus 0.5 billion cu. m from underground sources.

Agriculture in Turkmenistan is totally dependent on irrigation as all cultivable land is irrigated. The total irrigated area more than tripled in 30 years, increasing from 0.5 million hectares in 1965 to 1.7 million hectares in 1994 and remained stable afterwards (Figure 1.7 and Table 1.7). The irrigated area increased at a higher rate than the gross water intake. During the same period there were also improvements in terms of reduction of system losses. Between 1970 and 2004, water availability for agricultural needs increased only by 70 percent such that water use per hectare of irrigated land dropped by one half from 15 000 cu.m in 1970 to 7 500 cu.m in 2004.

Water reaches the agricultural producer through a complex system of primary canals to draw water from the rivers, secondary canals to distribute water to large farming units/peasant associations across the country, and tertiary canals to distribute water to farmers within the large units. In the end, the fields are furrow-irrigated with water from tertiary canals delivered through fairly primitive ditches. The entire system is open air and the canals are generally unlined.

The irrigation infrastructure is very widespread, however, its technical condition has been deteriorating for some time. Evaporation and filtration are the main sources of losses in the system, which may reach 70 percent of water intake because of the open-air system. Moreover, in the case of large-scale irrigation, there should be

collectors and other drainage facilities in place to remove excess water from the soil as otherwise the soil may become waterlogged due to a rising water table and its salinity may increase to levels detrimental to crop growing. The recommended density of collector-drainage canals is 45 meters per hectare, whereas the actual density in Turkmenistan is 19 meters per hectare, or 43 percent of the norm. The inadequacy of the collector-drainage network is reflected in severe deterioration of soil quality. In 14 percent of the irrigated land the water table has risen

above the critical level, 24 percent suffers from inadequate drainage, and 90-95 percent² of the irrigated land is salinized.

A recent approach to dispose irrigation from drainage water is the creation of the artificial Turkmen Lake in the middle of the Karakum Desert. Starting in 2009, the lake is being filled through two new collectors that divert up to 10 cubic km of saline drainage water, previously discharged into Amu Darya. The stated objective is that the lake's capacity will eventually reach 150 cubic km and provide a huge reservoir of water that will be recycled for irrigation after partial desalination treatment. However, field experience unfortunately shows the inflow is much lower than originally expected and that that irrigation with brackish or partially saline water is an environmentally bad solution, as under conditions of massive irrigation even low-salinity water gradually deposits a large amount of salt in the soil, leading to dramatic reduction of yields.

In addition to concerns with respect to the quality of the irrigation infrastructure, there are also concerns regarding the efficient use of water at the farm level. Water is exclusively owned by the state, which is entrusted with ensuring delivery and maintaining water quality. There are no volume charges for water and farmers are only required to pay 3 percent of their gross product to state-controlled irrigation agencies as a contribution to general maintenance and technical upkeep of water delivery systems: this payment is collected by the peasant association. The government absorbs the cost of water as part of its policy to control both input and product prices. As a result farmers have no financial incentive to use water efficiently.

Efficiency of water use can be improved by reducing losses in the irrigation system and by adopting water-efficient irrigation technologies such as drip irrigation, subsoil irrigation, sprinkling and others. Conventional water conservation methods designed to reduce losses include lining the canals with seepage-blocking materials and using pipes instead of furrow irrigation. More efficient water irrigation would allow Turkmenistan to increase its irrigated area and could lead to a potential reduction of system losses from 30 percent to 15 percent, increasing agricultural production by at least 30 percent.

2 National Environmental Action Plan of Turkmenistan (2002).

Agricultural production

All CIS countries experienced a decline in agricultural production during the early 1990s. This initial decline was attributable to the disintegration of the traditional Soviet production system. At the end of the 1990s, however, the transitional decline switched to recovery as the cumulative effects of market reforms became clear. The pattern of decline and recovery in agriculture for the five Central Asian countries is shown in Figure 1.8. The recovery in different Central Asian countries began at different times. In three of the five cases, Kazakhstan, Tajikistan, and Turkmenistan, the turnaround from decline to recovery came in 1998. In Kyrgyzstan and Uzbekistan, the turnaround came earlier, in 1995 and 1996, respectively. Uzbekistan and Turkmenistan in particular showed extraordinary growth.

However, we have to make a cautionary note to this recovery. For Turkmenistan, the growth estimates are based on national production statistics and these are not free from suspicions of manipulation. While it is tempting to attribute the observed growth in Turkmenistan to the effect of ongoing reforms, the truth may be less encouraging.

Prior to 1990, Uzbekistan, Turkmenistan and Tajikistan were characterized by a relatively high share of crop production and a correspondingly low

Figure 1.8. GAO in Central Asian countries, 1990-2007 (percent of 1990)

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

share of livestock production in their national product mix. Livestock production for these three countries accounted for slightly over 30 percent of gross agricultural output during the 1980s, whereas in the two other Central Asian Countries, Kazakhstan and Kyrgyzstan, as well as in the Russian Federation and Ukraine livestock production represented on average 55 to 60 percent of the total agricultural production.

After 1992, we observe a distinct convergence of the product mix in all countries (except Tajikistan; Figure 1.9): livestock production in Uzbekistan and Turkmenistan accounted for 45 percent-50 percent of agricultural output between 1992 and 2007, a percentage that is very close to the share of livestock in Kazakhstan, Kyrgyzstan, the Russian Federation and Ukraine. The relative increase in the importance of livestock in Turkmenistan and Uzbekistan since 1992 can be attributed to the growing role of individual farms as the rapidly growing private sector concentrated on livestock production, while extensive crops remained in the stagnating large-scale associations.

Crop production

Changes in cropping patterns. During the Soviet times, Turkmenistan was a cotton monoculture, ranking second after Uzbekistan in cotton production among the six cotton republics of the Former Soviet Union. Cotton accounted for more than 50 percent of the sown area. Another

Figure 1.9. Share of livestock production in GAO in Central Asia, with Ukraine and the Russian Federation shown for comparison (averages for 1992-2007)

Source: Interstate Statistical Committee of the CIS - CISSTAT (2009).

30 percent was planted with feed crops, which played an important role in crop rotation. Grain, mainly wheat, was grown on 15 percent of the cropped area.

The situation began to change rapidly after 1990 when the government stimulated wheat production in order to achieve a high degree of self-sufficiency. The area under cereals (mainly wheat) increased from 15 percent in 1990 to 50 percent in 1998 and it continued to grow to 60 percent of total sown area in 2008 (Figure 1.10). The increase in the share of grain area between 1990 and 2002 came at the expense of a relative reduction in cotton cropping, which dropped further from 51 percent in 1990 to less than 40 percent after 2002, but mainly due to a sharp contraction of the area under feed crops, which dropped dramatically from 27 percent in 1990 to less than 1 percent in 2008.

Despite the decline in the relative importance of cotton production, the actual area planted with cotton declined only temporarily in 1990-1997 owing to an expansion of the irrigated land. Today it is back to the 1990 level of 600 000 hectares, compared to 500 000 hectares in 1980. The area grown with grain increased from 130 000 hectares in 1980 to 190 000 hectares in 1990 and then skyrocketed to 1 million hectares in 2005-2006: a five-fold increase in 15 years, followed by a small contraction in 2007-2008 (Figure 1.11) (see Annex 1.7 for detailed data).

Figure 1.10. Share of area sown to cotton, grain, and feed crops 1980-2008 (% of total sown area)

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

Figure 1.11. Structure of sown area 1990-2008 ('000 ha)

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

Note that in 2002, statistics reported a substantial increase in the feed area from 50 000 hectares to 350 000 hectares in 2006 (Figure 1.11). Data from 2007-2008, however, show a reduction of the feed area to virtually zero, presumably because of a data revision in the Department of Statistics. Therefore, it is not clear to what extent the data correspond to the reality, especially for feed crop production.

Despite the decline in relative importance of cotton production, Turkmenistan remains a major cotton producer in the region. Cotton production accounts for 30 to 40 percent of total cropped land in Turkmenistan, Uzbekistan and Tajikistan. In terms of grain (primarily wheat) production, Turkmenistan has more than 50 percent of its cropped area in grain, compared to 40 percent of the cropped area in Uzbekistan and Tajikistan (Table 1.8).

Interestingly, the shift from cotton monoculture to diversified wheat-cotton agriculture may have contributed to the stabilization of water use (and water intake) during the last decade despite the continued increase of irrigated areas, as wheat uses 40 percent less water per hectare than cotton.

Crop production and productivity. Production volumes of cotton and grain remained fairly static during the 1980s, as did the land sown with these crops. Cotton harvests fluctuated around 1.2 million tonnes,

In fact, it may indicate that there was “pripiska”, practice from Soviet times of inflating reported numbers to meet the declared targets and thus satisfy the political leadership. However, if we refer to independent sources, production numbers of these staples are two, even four times less (Figure 1.13). The lack of confidence in grain statistics between 1998 and 2006 is strengthened by the huge downward adjustment published in the agricultural yearbook of Turkmenistan for 2006-2007. The 2007 downward adjustments are shown in Figures 1.12 and 1.14 by thin lines emphasizing the 2006-2007 discontinuity in the grain series.

Cotton production is found to be far more stable than grain production. The cotton harvest peaked in 1990 at an all-time high of nearly 1.5 million tonnes with yields of 2.3 tonne/ha (Figure 1.12 and Figure 1.14). Cotton output declined somewhat between 1990 and 1995 in direct response to the reduction of the area sown with cotton. The six years of stability came to an abrupt end in 1996, when cotton harvests collapsed to 435 000 tonnes (down from 1.3 million tonne the year before) and also cotton yields dramatically declined. Cotton yields never returned to the steady pre-1996 levels of 2.3 tonne/ha, staying below 1.5 tonne/ha (see Annex 1.9 for detailed data)

Livestock production

Livestock Inventories and Ownership Structure. Livestock in Turkmenistan is primarily sheep, cattle, and poultry. There have always been very few pigs in this Muslim country, and their number virtually dropped to zero in recent years as livestock production shifted mainly to the household level.

Prior to 1990, the number of animals showed a steady increase over time at roughly the same rate for all species (20 to 30 percent increase in headcount between 1980-1990). Between 1990 and 1997,

we witness a divergent trend: the cattle herd continued to grow, the number of sheep stagnated, while the poultry flocks shrank by 50 percent (Figure 1.15; for detailed data see Annex 1.10). A major turnaround came in 1997-1998, when the populations of all three livestock species boomed: the number of sheep bottomed out at 6 million in 1997 and then more than tripled to 18 million in 2007; growth of the cattle herd accelerated and even doubled from 1.1 million in 1997 to 2.2 million in 2007; and the biggest surprise came in the poultry subsector, where a sharp decline was reversed and the number of birds returned to the 1990 level in 2002. By 2007 the number of birds was more than double of the 1990 level. Aggregating the different species of animals into standard head (with one head of cattle equivalent to 10 sheep and 100 birds), we find that, due to rapid growth after 1997, the livestock herd in 2007 was almost four times larger than in 1980 and nearly three times larger than in 1997.

The rapid growth in livestock after 1997 is entirely attributable to the private sector. The cattle herd in the private sector more than doubled from 900 000 heads in 1997 to 2 000 000 heads in 2007. On the other hand, the collective and leased cattle in associations showed a continuous decline during the past decade. Overall, the private herd in standard heads increased by a factor of six between 1990 and 2007, while the number of animals in the state sector shrank to 50 percent of the 1990 level.

Prior to 1990, the collective and state farms accounted for 60 percent of the number of animals, whereas household plots owned 40 percent (Figure 1.16). The ownership structure began to change at an accelerating rate after 1990, and in 1998 the private sector (mainly household plots, but also daikhan farms) controlled 80 percent of all animals in the country. The relative growth of the private sector slowed down after 1998 but by 2007 it had reached 90 percent of the livestock herd.

Two policy factors appear to be responsible for the marked increase in livestock production after 1997. First, the government abolished the limits on the number of animals and poultry that households were allowed to keep. Second, the government exempted meat and milk production from state orders and permitted livestock products to be sold freely at market prices.

Figure 1.15. Livestock headcount by species 1990-2007

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

Figure 1.16. Changing ownership structure of the livestock herd by farm type 1980-2007 (%)

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

Livestock production and productivity. Livestock production has registered impressive growth since 1990. The production of milk grew almost by a factor of five from 436 000 tonnes in 1990 to 2 100 000 tonnes in 2007, and the production of meat tripled in the same period (from 103 000 tonnes to 300 000 tonnes). Table 1.11 presents the production data for selected years. The detailed meat and milk production series are given in Annex 1.11.

The growth in physical output did not always match the growth of the livestock resource base and we observe significant divergences in the productivity of milk and meat. Up to 1998 the growth in the physical milk supply generally matched the increase of the cow herd such that milk yields stagnated at 1 300 kg/cow. Since 1998, however, milk output has been growing faster than the number of cows, suggesting significant improvements in milk productivity. Between 1998 and 2007 milk output increased by more than 170 percent while the number of cows grew by only 60 percent. Milk yields accordingly rose from the pre-1998 level of 1 300 kg per cow to 2 000 kg per cow in 2006-2007. The gains in meat production, on the other hand, lagged behind the increase in herd size for most of the past decade. In recent years, however, we have also observed a steady improvement in meat yield.

Table 1.11. Livestock Subsector: herd and production in 1990-2007

	Cattle ^a	Sheep ^a	Livestock herd ^b	Meat ^c	Milk ^d	Milk yield ^e
1990	829	5 481	1 451	103	436	1 315

a thousand head, b thousand standard head, c thousand tonne (slaughter weight), d thousand ton, e kg per cow per year, calculated as the ratio of milk production to total number of cows.

Source: National Institute of State Statistics and Information of Turkmenistan (various years).

Agricultural productivity. Productivity is calculated as the ratio of output to inputs used in the production of the output. Standard productivity measures are the partial productivity of land and the partial productivity of labour. Since GAO growth exceeded the growth of land resources and lagged behind the growth of agricultural labour, partial productivity of land increased between 1990 and 2007 (by 17 percent), while partial productivity of labour decreased during this period (by 11 percent).

However, one should be careful interpreting these results as the rapid growth of gross agricultural output is suspicious. Therefore, it is most likely that the growth in overall productivity is overestimated.

||||| Agri-food markets and services

This chapter analyzes agricultural output and input markets in Turkmenistan. The first section compares the size of the state and private sector in terms of agricultural output. The second section analyzes the state system of parastatal input and service provision.

The role of the state and private sector in input and output markets

The state sector controls the production of four strategic crops — cotton, wheat, sugar beets and rice — plus a small share of the livestock production in peasant associations and other agricultural enterprises, much of it owned by the vertically integrated state livestock organization, Turkmenmallyary. The rest of the agricultural production in Turkmenistan is produced in the private sector (household plots and daikhan farms) (Table 2.1). The value of commodities produced in the state sector in Turkmenistan is relatively small with only 24 percent of total GAO, 41 percent of crop and 11 percent of livestock production.

Sales of agricultural commodities in Turkmenistan are differentiated into the state and the private sector, but the size of these sectors is unknown a substantial share of the production, as in the private sector, is for own consumption. Leaseholders operating in the state sector are obligated to deliver all their production to parastatal procurement organizations so that the marketed production in the state sector does not differ from the production.

In order to obtain an estimate of the own consumption in the private sector, we use an estimate of on-farm consumption which is equal to the consumption norm from the Soviet Union recommended by the Turkmen Ministry of Agriculture (MoA). Using these consumption norms most likely results in an overestimation of the actual on-farm consumption and hence an underestimation of the marketed

production from the private sector. Table 2.2 contains estimates of marketed production for the private sector. In 2006-2008 the average marketed portion was about 42 percent for vegetables, melons, potatoes and grapes and 32 percent for milk, beef and veal and eggs.

The value of production from the private sector in 2007 is reduced in accordance with this adjustment. Applying the “marketed portion” for privately produced commodities—about 42 percent for crops and 32 percent for livestock products—to “other crops” and “livestock” products from daikhan and household farms in Table 2.1, we can derive values of marketed production for the private sector (Table 2.3). According to Table 2.3 the private sector provides 52 percent of total marketed GAO, 37 percent of the value of marketed crops and 72 percent of the value of marketed livestock products.

Table 2.1. The state and private agricultural production sectors of Turkmenistan, in 2007 (billion manats, % total)

2007

Output and input markets in the state sector

The agricultural reforms of 1996-1997 removed the managerial authority from the MoA and the kolkhoz system to a new system of parastatal service and procurement organizations.³ Furthermore, the scope of state agriculture was narrowed to the production of only three strategic crops (cotton, wheat and rice). In 2000 sugar beets were added to the list of state order crops. State orders for meat and milk were dropped, and private trade was developed for non-state order crops.

The essence of the centralized state planning system (“goszakaz” or state orders) for production of the four strategic crops is that planning, input and service delivery, as well as procurement for the four strategic crops is carried out on the basis of Presidential Decrees and government resolutions. Neither peasant associations nor their leaseholders make decisions on the production of these crops. Input and service delivery for these crops is provided by the Ministry of Water Economy, Daikhanbank and five parastatal service organizations for agriculture. These organizations make up the State Agricultural Joint Stock Company of Turkmenistan formed in 2004 by Presidential Decree. The parastatal organizations are responsible for delivering a standard package of inputs to each leaseholder calculated on a per hectare basis and collecting a standard expected output based on a standard yield. Information on each of these organizations and their role in the state planning system can be found in Annex 2.

The state order system utilizes the vast majority of land resources in Turkmenistan. In 2008 state production of wheat and cotton represented 89 percent of total sown land in Turkmenistan and even 92 percent of the total cultivable area (Table 2.4).

3 Until 1997 the Ministry of Agriculture was the central institution for the organization and management of agriculture. As a result of the 1997 reforms the functions of the Ministry of Agriculture were severely restricted. Its system of local offices was transferred to regional (velayat) and district (etrap) level administrations, and responsibilities for the management, financing and servicing of farms were transferred to the new parastatal input service and procurement-based organizations.

Food processing

This chapter analyzes the food processing industry in Turkmenistan. First, we discuss the role of agri-food processing in the overall economy and its performance. We discuss in detail the main processing sectors: vegetable oil, flour milling and bread baking, meat and dairy industry, and vegetable and fruit canning. Second, we discuss the relative importance of state and private food processors. Finally, we discuss two case-studies of important supply chains in Turkmenistan in more detail: flour milling and baking and dairy.

Importance and structure of the food processing industry

Importance of the food processing industry

The food processing industry in Turkmenistan accounts for 9 to 10 percent of GDP, with cotton fibre (a component of the light industry) adding another 1 to 2 percent of GDP over the years (data for 2000-2007). The share of agri-food processing in GDP is thus about half the share of primary agriculture (Figure 3.1).

Figure 3.1. Share of agriculture and agri-food processing in GDP, %

*Data for ginning in 2001 are missing.

Source: Stanchin (2010b), Tables 1, 8.

Data on the aggregate value of food processing in constant prices are available only for the early years of independence (Statistical Yearbooks of Turkmenistan, 1996; CIS Interstate Statistical Committee of the CIS - CISSTAT 14, 2009). These data reveal a sharp decline in the food processing industry in the early 1990s. By 1996 the food processing industry had dropped to 70 percent of the 1990 level. There are indications of stabilization and possible recovery in 1996-1998 (the last years for which aggregate value data are available from the CIS statistical source), so that the general behaviour of food processing in the 1990s was similar to the behaviour of the primary agricultural production where, after a sharp decline in the beginning of 1990s, there was renewed growth after 1998 (see Chapter 1).

In the absence of aggregated data on the food industry, we consider the disaggregated growth of the main food processing products in physical quantities (Table 3.2). Between 2000 and 2008, processing output increased substantially for vegetable oil, canned fruits and vegetables, and especially non-alcoholic beverages. Meat processing and flour production remained essentially flat while dairy output declined sharply. The production of bread and baked products increased impressively over time despite the constancy of domestic flour production, presumably augmented by flour imports. Table 3.3 gives the growth in food processing expressed per capita.

In May 2010, the National Program of Socio-economic Development of Turkmenistan 2011-2030 was adopted to improve the food security of the Turkmen population. In this plan there is a substantial increase in both the primary agricultural production and the processing industry envisaged (Table 3.4 and 3.5). These projections estimate that the growth of the agri-food processing industry will exceed population growth such that there is high per capita growth of the agri-food processing industry. In order to achieve this growth, it is foreseen that in the period 2010-2015 state investments in the agri-food processing industry will be tripled compared to the period 2005-2009 (Table 3.6). However, despite these planned investments, it is unclear to what extent these data are credible and especially for meat, dairy and flour milling the projected growth is much higher than the growth achieved in the past decade.

In May 2010, the National Program of Socio-economic Development of Turkmenistan 2011-2030 was adopted to improve the food security of the Turkmen population. In this plan there is a substantial increase

in both the primary agricultural production and the processing industry envisaged (Table 3.4 and 3.5). These projections estimate that the growth of the agri-food processing industry will exceed population growth such that there is high per capita growth of the agri-food processing industry. In order to achieve this growth, it is foreseen that in the period 2010-2015 state investments in the agri-food processing industry will be tripled compared to the period 2005-2009 (Table 3.6). However, despite these planned investments, it is unclear to what extent these data are credible and especially for meat, dairy and flour milling the projected growth is much higher than the growth achieved in the past decade.

Importance of different subsectors

Meat and dairy processing accounts for over 15 percent of the food industry, while flour and other milled products represent only 6 percent (Table 3.7). The remaining 80 percent represent a mixed category of food products that includes vegetable oil, confectionary products, non-alcoholic beverages, etc. (no breakdown available).

Cotton sector. As the result of an increase in cotton yields, the cotton harvest has grown since 2002 (see Chapter 1). This has naturally led to growth in cotton ginning, cotton seed production and cotton-seed oil production, which together represents nearly the total vegetable oil production in Turkmenistan (Figure 3.2).

All cotton is ginned into fibre, which is then exported to the world market. A small portion of cotton seeds extracted during ginning (about 15 percent on average) is retained by the purchasing agencies for next season's sowing, and the remaining 85 percent is processed into vegetable oil, which is then sold to consumers either by the processors or by the farmers who receive a share of the oil as additional payment in kind for their cotton. All cotton gins and oil pressing plants are state owned.

Flour milling and bread products. All wheat is consumed domestically, and about 70 percent of the wheat production is milled into flour; another 20 percent is used as seeds for next year's sowing and around 10 percent is fed to animals (averages for 2007-2009). Flour production has remained essentially flat at a level of 550 000 tonnes since 2000 (Table 3.8), up from about 450 000 tonnes in the decade 1990-1999. The stability of flour production is inconsistent with the reported increases in wheat production (see Chapter 1). As indicated before, however, these data on the evolution of wheat production seem unreliable.

Role of the state and private sector in food processing

All food processing companies were state owned in 1990 and have not been privatized during transition. Yet private processors (usually small-scale) emerged in all sectors of the food processing industry including meat, dairy, vegetable canning, milling and bread baking. Table 3.9 shows the number of processors by ownership type in the main sectors of the food processing industry. The information is probably fairly reliable for state processing plants and plants operated by the state-controlled consumer cooperative system. Nevertheless, it is unreliable with respect to private processing plants as it only lists the formally registered legal bodies.

In the absence of explicit statistics, the share of private processing can be estimated by taking the difference between the total output of the processing industry and the reported output for state processors (both variables are published in official statistics). Figure 3.6 shows the corresponding estimates for the shares of state and private processing in major product categories (averages for 2005-2009). Except for flour

Table 3.8. Structure of food processing industry by ownership (2009)

Source: Stanchin (2010b), Table 12.

and other milled products, which appears to be a virtual monopoly of state processors, the share of private processing ranges from 30 to 50 percent for meat and dairy products to 80 to 90 percent for bread baking and canned vegetables. The private sector was traditionally strong in bread baking and fruit and vegetable processing: even back in the 1990s households produced up to 60 percent of bread and processed fruit and vegetables.

Although private processing dominates bread baking, canned vegetables, meat, and even dairy, it is noteworthy that the share of state processing has been steadily increasing between 2005 and 2009 (Table 3.10). The trend is even noticeable for bread and canned vegetables where overall the role of the state sector has been minor. In these two product categories the share of the state sector increased from 16 percent to 23 percent for bread baking and doubled from 8 percent to 16 percent for vegetable canning.

The agri-food processing industry obtains its raw material mainly from the domestic market. The production in household plots and daikhan farms (basically meat, milk, fruits and vegetables) is free from

Figure 3.6. Shares of state and private processors in Turkmenistan’s agri-food processing, averages for 2005-2009

Milled includes flour, groats, macaroni; dairy excludes butter (100 percent state).
Source: Stanchin (2010b), Tables 18, 29, 43.

farms—maintain a dominant position, the total production of the state sector is sufficient to supply less than 40 percent of the processors' requirements for raw milk and less than 60 percent of the requirements for animal carcasses (Table 3.12).⁴

To ensure supply of raw materials from a multitude of small farms, the processing industry should adjust the structure of its collection channels so that it matches the fragmented production structure. Dairy and vegetable processing cannot operate without setting up adequate arrangements for collecting raw materials from small individual farms, including household plots. The decrease in dairy and meat processing, which occurs despite the continued increase in output of raw milk and meat at the farm level, is probably a symptom of the inadequate collection and delivery arrangements between the processing industry and small producers.

Table 3.10. Balance of uses of main commodities 2008

	Production, '000 tonnes ⁽¹⁾	Total marketed, % ⁽²⁾	Sold to processing, % ⁽³⁾	Sold to consumers, % ⁽⁴⁾	Consumed on farm ⁽⁵⁾
Cotton (2009)	1 050	100	100	0	0
Cotton seed (oil pressing)	558	n.a.	85	15 percent for seed	
Wheat	815.8	n.a.	70	20 percent for seed, 10 percent for animal feed	
Meat (incl. sausage)	282.8	16	12	4	84
Milk (incl. butter)	2065	45	7	38	55
Vegetables and fruits (excl. melons, grapes)	770.7	62	11	51	38

Sources: based on Stanchin (2010b) (columns 1, 3) and Stanchin (2010a), Table 26 (column 5); column 4 calculated by difference.

⁴ These numbers are overestimates as they assume that the state producers sell their entire output of meat and raw milk to processors, whereas in reality some of their output may be sold directly to consumers in local markets.

Figure 3.7. Schematic description of the wheat-to-bread supply chain

Source: interviews during the mission, imports data – USDA FAS.

Elevators. Elevator facilities are often co-located with flour mills and may also provide cleaning, inspection, and quality blending functions. After the collapse of the Soviet Union, the country had no silo (elevator) facilities and only a few mills. As such, Turkmenistan was seriously lacking grain storage facilities until recently. Since 2008 the country has launched a major expansion of its storage facilities.

Milling. About 80 percent of harvested wheat goes toward production of flour with only a limited quantity used for seeding and other purposes. In 2008 national flour production reached 500 000 tonnes. The primary product is wheat flour for baking, while the main by-product is bran (about 22 percent of output).

Half of milling facilities in the country are of medium size (200 tonnes/day). The government has made significant investments in the milling sector by adopting the latest technology (Buller and Petkus equipment) and progressively increasing flour milling capacity; and since Turkmenistan's independence, nine milling facilities of 350 tonnes/day capacity have been put into operation.

Processing into bread and macaroni products. There are nine large wholesale bakeries in the country. One of the biggest companies is Ashkhabad churyok, with a daily capacity of 140-150 tonnes. The pasta industry started operating only in 1994. Out of total flour production, 15 percent-20 percent (75 000-100 000 tonnes) are processed into macaroni products. This activity is under state control (95 percent). Products include macaroni, bran, and semolina. In addition to the state sector, there is also a substantial private sector, specialized in bread baking.

Investments in the milling and bread industry. Cumulative investments in the milling industry between 2005 and 2009 reached USD 124.4 million, all financed with state funds. An additional USD 203.8 million is planned to be invested through Turkmengallaonumleri, the grain sector parastatal, up to 2012. Box 1 lists the planned investment projects until 2012.

New elevators and mills are being constructed in each province: a grain elevator with a capacity of 50 000 tonnes was put into operation in Ruhubelent Etrap in Dashoguz Velayat; another two were built by IKR Babolna (Hungary) in Ahal Velayat: a 30 000 tonne elevator in Kaahka Etrap and a 50 000 tonne elevator in Altyn Asyr; and an

elevator with capacity of 50 000 tonnes in Yoloten Etrap, Mary Velayat. Under this programme, Turkmengallaonumleri plans to achieve a total of 350 000 tonnes of storage capacity and 1 320 tonnes per day for milling capacity.

Constraints for grain sector development. A major constraint for the development of the grain sector is the state control of production. Leaseholders in the peasant associations have no control on which seeds they will use, when they will plant them, the fertilizer and pest control agents they will use, when they will harvest etc. In addition, the input and output prices are determined by the government and while inputs are subsidized, state procurement prices for agricultural output are below international prices, such that in fact producers are subjected to net taxation (see Chapter 5). Furthermore, the poor quality of the raw material produced is a constraint for the development of the grain sector.

Dairy supply chain⁶

The stock of cattle in Turkmenistan is about 2.2 million head (2009) of which 1.04 million (or 47 percent) are milking cows. Half of Turkmenistan's cattle is concentrated in Dashoguz Province in the north, owing to better fodder availability. More than 90 percent of the livestock herd is in the private sector (see Figure 1.16) and overall the state plays

⁶ This section is based on Punda (2010a).

Box 1. Investments plans of Turkmengallaonumleri up to 2012

A diversified mill complex in Rukhabat district, Akhal velayat, capacity 80 000 tonne. The complex will include:

- A grain elevator with 100 000 tonne capacity;
- A bakery with capacity of 40 tonne/shift;
- A plant for macaroni products (48 tonne/shift);
- A plant for manufacturing of polypropylene bags (18 million bags a year).

Six grain elevators in Akhal, Balkan, Dashoguz, and Lebap with 30-50 tonne capacity.

Four mills in Balkan, Dashoguz, Lebap, and Mary with milling capacity of 50 000-80 000 tonnes and grain elevator capacity for 50 000-100 000 tonnes.

Nine industrial bakeries in medium and small towns across the country with capacities from 2 500 to 14 000 tonnes of bread and baked products.

Source: Stanchin (2010b).

farmers receive from the state (Table 5.6). This adjustment is quite small compared to the previous price gap calculation and does not affect the calculations profoundly.

For the years 2005 to 2009 producers of cotton and wheat were taxed by the state procurement system, though taxation declined in the last few years because of the abolishment of the non-market exchange rate.

Investment policy

The Turkmen Government supports agricultural investments in two ways: first, by providing direct investment subsidies and second, by providing credit programmes, where investors can lend money at preferential interest rates. These programmes will be discussed in the first two sections. Then we will discuss the Turkmen policy concerning foreign investments.

Direct investment subsidies

All large investments in Turkmenistan, including both state and private investments in the agricultural sector, can be implemented only after approval by the President of the Republic. Together with permission for investment the investor receives a plot of land as well as subsidies, privileges and other eligible support.

The most revealing example of the state investment program in agriculture is the rural development program, which will be analyzed in section 5.6. However, there is also state support for private investment in the agricultural sector and the most recent example of this is the construction of the poultry producing and processing company, Gush Toplumy, belonging to the chairman of the Union of Enterprises and Entrepreneurs. In June 2007 the President signed a decree, which provides substantial financial support to this private company. The company got 30 ha near the capital city and was attributed a preferential loan. In addition, another two ha of land in two veloyats were allocated for feed production. Finally, the company was exempted of all customs duties until the end of the construction and of all taxes for poultry meat and products until 2010.⁴³

43 www.turkmenistan.ru, 17.9.2008.

Finally, there exists also a program of preferential credit (5 percent of interest) for investment business projects by private entrepreneurs, which are selected by a special committee. The loans can be provided both in manat and in hard currency. Hard currency loans are dedicated for import of equipment which is not manufactured in Turkmenistan. These loans are provided for the period up to ten years.⁵² The food industry already benefited before from such a credit program and it is expected that from 2010 on the interest rate will be reduced to 2 percent.⁵³

Foreign investment

Foreign investments are determined based on tenders, but they can also be determined by intergovernmental agreements between Turkmenistan and other countries. The sectors of the national economy to which foreign investment are attracted are: wholesale and retail trade, manufacturing industry, construction, agriculture, hunting, forestry and services. Foreign investment in the agricultural sector is concentrated mainly in the grain and cotton processing industry, the food industry, and the textile, silk and carpet industry.

The German Unionmatex GmbH builds in Turkmenistan milling complexes with a total investment cost of 1 444 million euro. The largest milling complex has an investment cost of 56.8 million euro (elevator with capacity of 100 thousand tonnes, mill for 80 thousand Lourdes a year, processing facilities for 40 tonnes of bread products and 48 thousand pasta a day, 18 million of polypropylene bags a year and a modern retail centre) will be built near Ashgabat. The second largest milling complex has a cost of 28.1 million euro and will be built in Turkmenabat. The remaining three complexes have an investment cost of 19.7 million euro each and will be built in three provinces.

The joint stock company IKR Babolna (Hungary) won the tender for construction of elevators, with a total investment cost of USD 31.6 million. The Turkish Polimeks Insaat Tahhut we Sanai Tijaret A.S. designed and built a vegetable oil plant near Ashgabat with a processing capacity of 300 tonnes of cotton seeds per day, an investment of USD 67.9 million. Recently, the association of the Food Industry announced a tender for the construction of three processing plants: a tomato canning factory and two oil extracting factories.

53 Association of Food Industries, Bereketli company and Sut dairy plant.

Trade policy

Overall, Turkmenistan is poorly integrated in the international markets. There are several reasons for this. First, both internal wholesale trade and foreign trade is highly controlled through a number of means. Annex 3.1 contains a list of legislative documents that constitute the legal basis for state regulation of national and foreign trade. The main means of regulation of foreign trade in Turkmenistan falls into the following broad categories: state procurement, trading and licensing, import and export tariffs (tariff barriers to trade), sanitary and phytosanitary measures (the SPS measures) and technical barriers to trade (TBTs). Second, Turkmenistan is not a partner in any existing international or regional multilateral trade system.

State regulation of national and foreign trade

State procurement, trading and licensing. The first means of control is through the State Commodities and Raw Materials Exchange (See Stanchin, 2010b, pp. 53-55). All wholesale and foreign trade contracts are required to be registered and processed through this exchange. The charter of the Exchange defines the procedures of registering and processing purchases and sales, the type of transactions permitted, the informational requirements for all transactions, the procedure for price quotations and the method for deriving an orientation price for frequently traded goods, accounting procedures for entering transactions into buyer and seller accounts, procedures for avoiding large price fluctuations, cartels and other price distorting mechanisms.⁵⁴ The contract registration procedure includes an assessment of the contract price (i.e. customs valuation). All import contracts must be registered before goods are delivered to Turkmenistan. Any physical or legal person, state or private, can trade on the State Commodities and Raw Materials Exchange. However, there are considerable bureaucratic barriers to registering contracts on the exchange such that small individual farms do not often deal on the exchange.

In addition to the State Exchange, the Turkmen Government uses licensing to control production and trade for a number of products. Registration with the Ministry of Economy and Development for all juridical and physical persons engaged in foreign trade was obligatory until 2009. The August 2009 Law of Turkmenistan "On state support

⁵⁴ The functions of the State Exchange are listed in the law "On the Commodity and Raw Materials Exchange".

for small and medium entrepreneurship” exempted small and medium business from obligatory registration related to foreign trade.

Production licenses are currently required for 44 types of activity in Turkmenistan, of which six relate to agriculture. The same organizations also issue import licences for the products under their responsibility. The Association of Livestock joint stock companies, Turkmenmallyary, grants licenses for the domestic and foreign sale of karakul sheep in addition to licensing trade in breeding animals. The MoA grants licenses for seed selection and imports. The Association of Food Industry of Turkmenistan grants licenses for activities in the area of production and sales of food and feed. Trade in fishery products, alcoholic beverages, spirits, and tobacco products is also subject to licensing.

Tariff barriers to trade. Turkmenistan uses both export and import tariffs to regulate trade. In the presence of effective direct controls over foreign trade described above, tariff policies are relatively unimportant as a tool for regulating trade in Turkmenistan.

Exports of 12 product categories, including tobacco, alcohol, fresh vegetables and melons (July-August period only) are exempt from export taxes. On the contrary, nitrogen fertilizers, wheat, wheat flour, rice, ice cream and other products are currently subject to various export tariffs (duties).

Eight product groups, including cereals, flour, meat, eggs, butter and some other products are not subject to any import tariffs or quantitative import restrictions in Turkmenistan. At the same time Turkmenistan imposes import tariffs on honey, grapes, cotton oil, processed meat products, mineral water and other food products. Ice cream faces both import (USD 0.5/1 kg) and export (USD 0.2/1 kg) tariffs. The lists of goods subject to import and export tariffs/duties and their rates, as well as products that are exempt from import and export duties, are provided in Annex 3.2. The extent of tariff cover of different products is not excessive; therefore, it is not clear what import and export tariffs are applicable to the products not explicitly mentioned in Annex 3.2.

Effective tariff cannot be estimated because different lots of traded commodities are imported under different terms. The Turkmen private business does not consider customs duties excessive⁵⁵, however

⁵⁵ Information obtained from the interviews with a number of the managers of private companies.

trade regulation together with the internal barriers for entrance to food market can form a rather high effective tariff.

According to the Law of Turkmenistan “On state support for small and medium entrepreneurship” (2009), all SMEs are freed from payment of any tariffs (Stanchin (2010b), p. 57).

SPS and Technical Measures. Import of cattle, sheep, goats, camels and pigs requires a permit from the Cabinet of Ministers⁵⁶. Specific regulations based on which the import permits are granted (e.g. the list of quarantine pests) were not available at the time of report writing. The MoA of Turkmenistan, through its Plant Protection and Quarantine and Veterinary Services, is responsible for animal and plant health while most aspects related to human health and safety fall under the responsibility of the State Sanitary and Epidemiological Service of the Ministry of Health of Turkmenistan.

Membership in international organizations and conventions

Turkmenistan is not a partner of any existing international or regional multilateral trade system. It is also the only country of the Former Soviet Union that has not applied for membership in the WTO. Although none of Turkmenistan neighbours is currently a member, all neighbouring countries and major trading partners are in the process of WTO accession.

The country is a member of FAO, which hosts the International Plant Protection Convention Secretariat and provides support to the Codex Alimentarius Commission. However Turkmenistan is neither a signatory party to the International Plant Protection Convention or a member of the Codex Alimentarius Commission, both key entities for WTO trade issues. among all international organizations and treaties governing human, animal and plant health issues in the international trade, Turkmenistan is a member of only one: the World Organisation for Animal Health (OIE), which is the international standard setting institution for animal health and related trade measures. The country is represented in this organization by the Chief Veterinary Officer of the Ministry of Agriculture and Food. The country is a correspondent member of the International Organisation for Standardization (ISO), although it does not participate in any technical committee.

⁵⁶ Prikhodko (2010), p. 17.

Rural development

Rural development became a priority for agricultural policy makers in Turkmenistan under the new President. In 2007 a National Program of President on Enhancing of Living Standards of Population in the Villages and Settlements was adopted. The Program consists of three stages: 2008–2010, 2011–2015, and 2016–2020 and budget of 72.5 trillion manat (USD 25.4 billion or per year 20 percent of the national budget).⁵⁷ The program aims income growth and increased rural employment as well as improvement of living conditions on the countryside.⁵⁸

⁵⁷ President's National Programme for livelihoods improvement in rural areas till 2020.

⁵⁸ Ibid.

||||| Conclusions and implications for the EBRD

Ambitious GDP and food processing projections are a sign that there may be opportunities for EBRD assistance in Turkmen food processing in the next ten years (Table 6.1). One of the key challenges is to ensure the growth of a downstream processing, distribution and retail sales sector so that the sector expands by adding value to primary production. As economic production moves up the value chain, the result is more and higher paying employment leading to growing per capita incomes. At the same time, expanding the processing and retail sectors requires a constant supply of high quality raw materials and improved access of processing companies to raw materials, which in the case of meat, dairy and fruits and vegetables, are mainly produced by small household farms.

Institutional limitations for investment

While there may be opportunities, the constraints for investment in Turkmen agri-food processing are numerous. First, accurate information on the sector and on the financial state and performance of individual enterprises is not publicly available in Turkmenistan. Investor decision-making is extremely difficult and limited in such an environment. On the sector level, the information for this review was gathered in the face of great difficulties exceeding those in other CIS countries, including Belarus and Uzbekistan. The first meeting of the research team with officials of the National Institute of Statistics and Information yielded no information on the sector. On the level of the enterprise, information on the financial state of companies is currently available only on an ad hoc anecdotal basis through interviews and only through the good will of the company. Financial information on companies in Turkmenistan has traditionally been considered as an instrument of state monitoring, primarily for tax collection and undisclosed statistical purposes, and a resource to which access was restricted. Likewise, audits are associated more with tax compliance than with an independent financial statement

Moreover, there are only limited institutions supporting the private sector. There are no private commercial banks in Turkmenistan, only state banks, and the availability of credits for entrepreneurial activity outside of the state order system is quite limited because banks are not adapted to servicing small businesses. There are no private accounting companies, only a state audit bureau within the Ministry of the Economy. Tax legislation is ill-adapted to a market economy. There is no stock market, nor is there a currency exchange. Though a State Raw Material and Commodity Exchange functions in Turkmenistan, its chief purpose is more one of control rather than encouraging foreign and wholesale trade. All wholesale and foreign trade contracts are required to be registered and processed through this exchange. And while any legal or physical person can sell on the exchange as long as it registers, the registration process is usually a cumbersome process, involving approval from various agencies.

Third, there is only limited information on state of basic institutions in Turkmenistan and it is unclear what the situation is with respect to ownership rights, the security of these rights, and contract enforcement, which are crucial issues for both domestic and foreign investors. It seems that some decisions are been taken at hoc (e.g. sudden confiscation of land from the daikhan farms based on farm performance despite strong growth of the private sector), which implies risks and uncertainties.

Fourth, foreign trade of the country is effectively controlled by the state through the requirement of registration of every wholesale and export-import contract on the State Raw Material and Commodity Exchange. Thus, the Turkmenistan economy is relatively isolated. Exports are dominated by gas, oil and oil products, with virtually no manufactured goods. While domestic incomes are set to increase rapidly over the next 20 years the Turkmen domestic market is small compared with the Russian Federation and Ukraine.

The above limitations narrow the potential scope of EBRD operations in Turkmenistan. Without a more supportive legal environment for accounting information for companies, equity participation on a large scale would be risky. Perhaps the situation will change after 1 January 2014 when enterprises in Turkmenistan are supposed to complete the transition to international standards, but for now large scale equity participation in companies is difficult. Moreover, processing companies of strategic commodities (cotton, milling, vegetable oil) are state-owned. These companies are difficult for EBRD investment.

Hence, the most likely recipients of investment in Turkmenistan are private SMEs in livestock production and meat and dairy processing, baking, fruit and vegetables production and processing. In addition to processors in non-strategic agri-food sectors, investment in private SMEs in the confectionary sector, beverages (such as juice) and retail food stores would be warranted given the projected growth in Turkmen income.

Since there are no private banks, it is not possible to extend loans through local banks using a credit line. And since there are likewise no equity funds, this option is also ruled out. Limited direct loans from the EBRD to private SMEs introducing technical assistance seem to be the most likely modality for investment in the Turkmen private sector at this time.

Investment in non-strategic sectors

The concerns of the previous section imply that one of the main areas of investment in the Turkmen agri-food sector that may be of interest to the EBRD are loans to private SMEs in non-strategic areas and food retail chains. Within this group it seems that retail food stores would have the least risks associated with state regulation and exposure to small scale agriculture, while for SME food processors these are the two main risk factors that may impact their operations (Figure 6.1).

Figure 6.1: Two types of risk for SME investments in the Turkmen agri-food sector

Influence of state regulation

Agriculture and food industry are the national priorities for which the state aims to attract to state and private investments, mainly in the grain and cotton food chains, carpet, silk and textile industries and processing of fruits and vegetables. Overall, the government seeks no financial resources but rather technological knowledge transfer. State support is established to secure these investments and to reduce sovereign risks. Private investors in Turkmenistan have access to privileged credit with very low interest, sometimes negative interest in real terms. Foreign investments are possible only after presidential permission.

A major concern of investing under conditions of distorted economic proportions in Turkmenistan is the risk of inefficient technology, especially in non-competitive sectors. Therefore investment decisions should be designed in shadow prices as many of the sectors and enterprises can appear inefficient in a real economic environment.

Even in non-strategic areas of the agri-food sector there are risks associated with exposure to state regulation and competition from subsidized state processors. Figure 6.1 provides a schematic visualization of these risks. For instance, all food processors are subject to state GOST standards, which are not well adapted to the operation of a market economy. It may be argued that the difficulties of GOST standards are most acutely felt in more innovative production and packaging sectors since GOST standards are highly prescriptive and mandatory, specifying the materials, processes, analytic methods and techniques, and final product characteristics including packaging for all processed products. In baking, juice and confectionary production the exposure to GOST seems to be less, since production in these sectors is not so innovative. However, the processing of fresh fruits and vegetables into jams, juices and canned foods seems to involve a greater exposure to GOST standards, stifling innovation in products for the market and packaging. In the dairy and meat processing sectors GOST standards become more intrusive, since they stipulate the permissible ingredients, processes and final product characteristics in a sector that tends to be more innovative, producing various types of yogurt, kefir, cheese, sausages and other processed foods.

Although the risks with respect to state involvement associated with GOST standards are considered to be relatively low in the baking, confectionary and retail industries, there are other risks with respect to state involvement as in general, these sectors depend

for their procurement of several of their inputs on the state sector. For example, the baking and confectionary industries depend on the supply of raw material, respectively flour and sugar, from the state sector; or on imports, which are also controlled by the state sector. Hence, these processing companies are also strongly dependent on the state sector for the supply of their raw material.

Finally, private food processing plants in Turkmenistan face strong competition from the state sector and it will be difficult for private processing companies to compete with state owned processing companies which can operate with a loss thanks to subsidies. Moreover, the investment plans of the Food Industry Association should be taken into account when making loans to food processors, because the planned construction and reconstruction of processors is likely to use subsidized credits from the state banking system, which may offer better terms than the EBRD.

Dependence on small scale private agriculture

Food processing companies face difficulties with obtaining a constant supply of raw materials. Baking and confectionary enterprises work with already processed inputs such as flour, sugar and chocolate powder, which can be easily obtained and stored. However, ensuring a constant supply of fresh fruits and vegetables, milk or animal carcasses presents problems both for procurement and for storage. Lending to SME meat processing plants, fruit and vegetable plants and dairies will require technical assistance to processors not only in international accounting standards, but also with respect to developing methods for ensuring a secure and constant supply of raw materials from private farms. This may take the form of farm assistance programs, which could include training quality and food safety issues at the farm level, assistance in setting up of milk collection points, advisory services for animal nutrition and agronomic advice. The direct and indirect effects of farm assistance programmes can lead to improved input access, productivity, product quality, and market access for small farms. These programmes have been an engine of productivity growth in the agri-food supply chains, supporting productivity growth from primary agriculture to marketing to consolidation, processing and distribution.

However, there are numerous challenges to applying this approach in Turkmenistan. First, there is a far larger state sector than in the other CIS countries, which has preserved state input supply and

procurement. The degree of state dominance of this sector would seem to prohibit the establishment of private standards and farm assistance. Second, state controls over production and trade for all but SMEs seem to be widespread. All wholesale and foreign trade contracts are required to be registered and processed through the State Commodity and Raw Materials Exchange. Third, there is currently no facilitating legislation for marketing cooperatives in Turkmenistan, a significant drawback for the collection and organization of the supply chain for agricultural raw materials.

Overall, these challenges make investments by the EBRD in the agri-food industry risky, although the potential turnover could be relatively high given the expected population and real GDP per capita growth. Nevertheless, it could be useful for the EBRD to enter a policy dialogue with the government of Turkmenistan to persuade them to reduce state control and to allow market institutions to develop, which would potentially attract private investors. Further, the Turkmen Government could remove regulatory issues specific to the agri-food sector that discourage investment. For example, it would be recommended to make the transition from GOST standards to more modern standards compatible with a market economy and the principles of the WTO international trading system, or to allow the establishment of marketing cooperatives.

1999 February	Presidential decree "On improvement of lease relations in agriculture"
2000 August	Presidential decree "On some measures regularizing land relations in Turkmenistan" [new organizational responsibilities for allotment of land]
2000 September	Presidential decree "On creation of Land Resource Service in the Ministry of Agriculture" [responsible for land monitoring, cadastre, registration, titling]
2001 August-December	Presidential decrees on the sowing of wheat, cotton, and rice in 2002 [state orders made optional for leaseholders; entitlement to subsidies conditional on acceptance of state orders]
2002 April	Presidential decree "On improving the mechanism of income distribution from cotton production" [ginning byproducts belong to producers]
2004 November	Water Code
2004 November	Land Code [incorporates private land ownership without any transfer rights, subleasing of state land by peasant associations but not by daikhan farms]
2005 January	Presidential decree "On measures for implementation of the Land Code"
2005 January	Presidential decrees (7040 and 7082) on transformation of three leading daikhan associations into joint-stock companies in response to leaseholders' request [increased operating independence and improved incentives]
2007 March	Law on Daikhan Associations
2007 March	Law on Daikhan Farm
2007 April	Presidential decrees (8496 and 8553) on development of a state program to ensure a high level of social and living conditions of rural and urban population [legislation with rural development impacts]
2008 January	Presidential decree on streamlining of market transactions and establishment of "Ak altyn" as an organization for procurement and sale of cotton

Annex 1.8. The puzzle of grain yields

The behaviour of grain yields in Turkmenistan between 1998 and 2006 is totally at variance with the yield patterns observed for other CIS countries. Taken since 1980, grain yields in CIS fluctuated year to year, but generally did not show pronounced trends either up or down. Ukraine, with its exceptionally fertile soil, consistently achieved the highest yields in CIS (median of 2.6 tonnes/ha between 1980 and 2008, a record that Ukraine shared with Moldova and, somewhat surprisingly, Kyrgyzstan). On the other hand, Kazakhstan was always at the bottom of the yield ranking, presumably due to the low quality of its semi-desert cropland, achieving median yields of 1.0 tonne/ha. The Russian Federation generally fell in the middle, with median yields of 1.6 tonnes/ha (the country showed a moderate upward trend from about 1.3 tonnes/ha in the early 1980s to about 2.0 tonnes/ha since 2005). Ukraine at the top and Kazakhstan at the bottom defined a band of median grain yields for CIS countries ranging from 1.0 tonne/ha to 2.6 tonnes/ha (Figure A1.1).

Up to 1993, Turkmenistan's grain yields fit within the upper part of the CIS band, between the Russian Federation and Ukraine; between 1993 and 1998 Turkmenistan's grain yields collapsed owing to a combination of sown area increases and production declines; and then in 1998 the yields began to rise rapidly to levels above 3 tonnes/ha, overtaking Ukraine by a wide margin (Figure A1.1). A look at the curve for Turkmenistan in Figure A1.1 (thick black curve) clearly suggests that the reported yields for this country between 1998 and 2006 are totally out of line compared to the rest of CIS.

Another view of the curious behaviour of grain yields in Turkmenistan since 1998 is obtained by a comparison with FAOSTAT data for Europe and other regions (Table A1.1). In 1998 the yields in Turkmenistan were 1.8 tonnes/ha, compared with 3.3 tonnes/ha for Europe in aggregate; by 2006 Turkmenistan's reported yields had closed the gap with Europe, reaching 3.6 tonnes/ha compared with Europe's 3.4 tonnes/ha. It is hard to believe that between 1998 and 2006 Turkmenistan, with its severely constrained water and fertilizer resources, experienced the kind of technological progress that was necessary to close the persistent gap with European yields and overtake the relatively more advanced countries of Central Eastern Europe.

Turkmenmally and the State raw materials exchange. Daikhanbank presented financial data on each leaseholder and on each peasant association to the peasant association director, the economic and statistics sections of the etrap administration.

At the beginning of the sowing season each leaseholder would receive a credit to pay for sowing from which he would be charged for seed material, plant protection agents, fertilizer, water and other inputs, as well as an account service charge. Since all inputs and their prices are supplied in strict compliance with state norms on a per ha basis, the credit can be calculated on the basis of the planned sown area. The leaseholder put up his own property as collateral for the credit. At the end of the season the leaseholder's account would be credited with the proceeds from the sale of his crop minus his debt.

From 2007 Daikhanbank stopped working directly with leaseholders and worked only with peasant associations. Currently Daikhanbank has 55 branches in each etrap centre and 400 sections in peasant associations with a total of 2400 employees.

Annex 3.1. Legislative basis for state regulation of national and foreign trade

Law	Date
On foreign economic activity in Turkmenistan	April 1993
On investment activity in Turkmenistan	April 1993
On foreign concessions	October 1993
On currency regulation	October 1993
On the Chamber of Commerce	October 1993
On certification of products and services	October 1993
On the Commodity and Raw materials exchange	September 1994
On food security	June 2000
On trade	July 2002
Tax code	November 2005, revised June 2008
On foreign investments	March 2008
On coal resources	August 2008
On invention and industrial samples	November 2008
On trademarks, service standards and geographical indications of source	November 2008
Merchant Fleet Code	November 2008
On quality and safety of food	April 2009
Sanitary code	November 2009
On the organization of licensing in Turkmenistan (Presidential Decree no. 10281)	February 2009
